Intune Remediation Troubleshooting

For Intune Remediations, use the workflow below when troubleshooting a device. It follows the remediation lifecycle from assignment through script execution, reporting, and the next scheduled evaluation.

High-Level Workflow

```
Intune Service
   |
   v
Policy Assignment
   |
   v
IME Policy Sync
(IntuneManagementExtension.log)
   |
   v
Scripts Downloaded
(C:\Windows\IMECache\HealthScripts)
   |
   v
Detection Script Runs
(AgentExecutor.log / HealthScripts.log)
   |
   +-- Exit 0 = Compliant --> Report Success
   |
   +-- Exit 1 = Issue Found
           |
           v
      Remediation Script Runs
      (AgentExecutor.log)
           |
           v
      Results Reported
      (HealthScripts.log)
           |
           v
      Next Scheduled Evaluation
```

A remediation script runs only when the detection script exits with code 1. If detection returns exit code 0, remediation is skipped.

Log Investigation Path

1. IntuneManagementExtension.log

Location

```
C:\ProgramData\Microsoft\IntuneManagementExtension\Logs\IntuneManagementExtension.log
```

Use this log to determine:

- Whether the device received the policy

- Whether IME successfully synced
- Whether the remediation assignment was evaluated
- Whether download or processing failures occurred

Useful search terms:

```
HealthScripts
Remediation
Policy
Assignment
```

Start here when you need to determine whether the device knows about the remediation assignment.

2. Verify Script Download

Check the remediation cache:

```
C:\Windows\IMECache\HealthScripts
```

A package is typically stored in a GUID-named folder containing the detection and remediation scripts:

```
C:\Windows\IMECache\HealthScripts\<GUID>\
    DetectionScript.ps1
    RemediationScript.ps1
```

- Confirm the scripts downloaded
- Confirm the content is the expected version
- Confirm the detection and remediation files are present

If the expected package is absent, focus on assignment, IME synchronization, or download processing.

3. HealthScripts.log

```
C:\ProgramData\Microsoft\IntuneManagementExtension\Logs\HealthScripts.log
```

This is the primary remediation-specific lifecycle log. Review it for policy processing, detection execution, detection output and exit code, remediation launch, remediation results, and status reporting.

```
Detection Script Exit Code: 1
Launching remediation script

Detection Script Exit Code: 0
Remediation skipped
```

4. AgentExecutor.log

```
C:\ProgramData\Microsoft\IntuneManagementExtension\Logs\AgentExecutor.log
```

Use this log for the PowerShell execution layer. Look for script output, exceptions, exit codes, access-denied errors, missing paths, registry errors, and execution-context problems.

Registry Validation

IME script policy data can be inspected under:

```
HKLM\SOFTWARE\Microsoft\IntuneManagementExtension\SideCarPolicies\Scripts
```

Use this area to confirm that policy data exists and to correlate package identifiers and updates. The internal remediation framework also records checkpoints under:

```
HKLM\SOFTWARE\US Bank\IntuneRemediations\<ScriptName>
```

Checkpoint values can help confirm the last detection and remediation results, run times, and script version.

Troubleshooting Decision Tree

Remediation never runs

- Confirm the device or user assignment in Intune
- Review IntuneManagementExtension.log
- Review HealthScripts.log
- Verify that the Microsoft Intune Management Extension service is installed and running

Detection runs but remediation never runs

Review HealthScripts.log for the detection exit code. Exit 0 means compliant and skips remediation. Exit 1 means an issue was detected and remediation should run.

Remediation runs but doesn't fix the issue

- Review AgentExecutor.log
- Review the script-specific error log, such as C:\Logs\IR\<logname>_ERR.log
- Check exceptions, access problems, validation failures, and user-versus-system execution context

Fastest Troubleshooting Path

1. HealthScripts.log

2. AgentExecutor.log

3. C:\Windows\IMECache\HealthScripts

4. IntuneManagementExtension.log

5. Registry checkpoint key

This sequence usually answers the key questions: Was the remediation assigned? Did detection run? What exit code was returned? Did remediation launch? What error occurred?
